1. Introduction

The PFC750 module is an industry standard half-brick AC-DC converter with PFC function, it can provide 750W output power at 390VDC output voltage.

High efficiency up to 96.5% and power factor up to 0.99, allowing case operating temperature range of -40°C to 100°C. An optional heat sink is available to extend the full power range of the unit. Fully protected against input BNI/BNO(Brown-In/Brown-Out), output over-voltage and over-temperature.

2. Pin Function Description

Note: Base plate can be connected to FG through M3 threaded mounting insert. Recommended torque 4-8Kgf-cm.

3. Electrical Block Diagram
4. Connection for Standard Use

The connection for standard use is shown below. An external EMI filter is recommended to reduce electrical noise. The bus capacitors (C1 and C2) are recommended to set 330uF (KMR series of NCC) or more. The TRF1 is used to limit input inrush current.

5. Test Set-Up

The basic test set-up to measure parameters such as efficiency and regulation is shown below. When testing the PFC750 under any transient conditions, please ensure that the transient response of the source is sufficient to power the equipment. We can calculate:

The value of load regulation is defined as:

\[
\text{Load reg.} = \frac{V_1 - V_2}{V_2} \times 100\%
\]

Where:
- \(V_1\) is the output voltage at 100% load.
- \(V_2\) is the output voltage at 10% load.

The value of line regulation is defined as:

\[
\text{Line reg.} = \frac{V_{HL} - V_{LL}}{V_{HL}} \times 100\%
\]

Where:
- \(V_{HL}\) is the output voltage of maximum input voltage at full load.
- \(V_{LL}\) is the output voltage of minimum input voltage at full load.

6. Features and Functions

6.1 Over Voltage Protection

This module has a continuous over voltage protection function. When output voltage reaches the condition of OVP, the converter will shut down the output until back to normal range.

6.2 Over Temperature Protection

The over temperature protection is built in this module to safeguard against thermal damage. Shutdown occurs when the maximum case temperature is exceeded. The module will restart when the case temperature falls below the recovery threshold. Please measures the case temperature at the center point of aluminum base plate.

6.3 Power Good Function

The PFC750 module provides a signal from ENA pin for power good function. The ENA pin would be pulled down to -Vout when the Vout is ready; otherwise, the pin would be open. The following circuit is an example circuit for reference.
**PFC750**

**Application Note V10**

6.4 Sequence Chart

The working sequence of PFC750 is shown below.

![Sequence Chart](image)

7. Input / Output Considerations

7.1 Input EMI Filter at the Power Module

Circuit as shown below represents the solution for EMI. The EMI filter should be placed close to the converter AC input pins, and the external output capacitors are chosen for suitable ripple handling capability.

- TRF1: Cement resistor (A5MC-100JK L3.5 A & A) or equivalent.

7.2 Hold Up Time

The capacitor C1 and C2 are used for hold up time function and output ripple current. The PFC750 supplies power to load by the energy stored in C1 and C2 when input power is interrupted. A typical configuration as shown below.

![Hold Up Time Circuit](image)

This function provides energy that maintains the output for 8ms hold up time. The capacitance in the application is recommended as follow (Allowable capacitance range: 660~2200uF).

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>Hold up time</td>
<td>8ms</td>
</tr>
<tr>
<td></td>
<td>330uF</td>
</tr>
</tbody>
</table>
7.3 Inrush Current Limiting Resistor TRF1
TRF1 resistor is used to limit the input inrush current, and it must be connected between R and +Vout. If the resistor is not connected, the power supply will not work. TRF1 is a cement resistor with overheat protect function, it should have greater withstanding capability to Inrush Current. TRF1 is recommended to set from 4.7 to 22 Ω.

7.4 Output Ripple and Noise
Output ripple and noise are measured with a 10uF E.L and 0.1uF ceramic capacitors across output at 20 MHz bandwidth.

The conventional ground clip on an oscilloscope probe should never be used in this kind of measurement. This clip, when placed in a field of radiated high frequency energy, acts as an antenna or inductive pickup loop, creating an extraneous voltage that is not part of the output noise of the converter.

Another method is shown below, in case of coaxial-cable/BNC is not available. The noise pickup is eliminated by pressing scope probe ground ring directly against the -Vout terminal while the tip contacts the +Vout terminal. This makes the shortest possible connection across the output terminals.

7.5 Output Capacitance
The PFC750 needs external capacitor to maintain output supply normally, the capacitance range is 660~2200uF. For good transient response, low ESR output capacitors should be located close to the output pin.
8. Thermal Design

8.1 Operating Temperature Range

The highly efficient design of Cincon’s PFC750 power module could operate within case operating temperature range from $-40\,^\circ C$ to $100\,^\circ C$. The de-rating curve could be given when ascertaining the maximum power that can be drawn from the module. The maximum power which can be drawn is influenced by some factors, such as:

- Input voltage range
- Permissible Output load
- Forced air or natural convection
- Heat sink (optional)

8.2 Convection Requirements for Cooling

The ambient temperature and airflow are required to make sure the module temperature below its maximum rating. Once the module is assembled in the actual system, the module’s temperature should be monitored to ensure it does not exceed $100\,^\circ C$ as measured at the center of aluminum base plate.

8.3 Thermal Consideration

The power module operates in a variety of thermal environment; so sufficient cooling should be provided to help ensure reliable operation. Heat is transferred by conduction, convection and radiation to the surrounding environment. The power output of the module should not be allowed to exceed rated power ($V_{oc\,set} \times I_{o\,max}$).

8.4 Power Derating

The operating case temperature range of PFC750 is $-40\,^\circ C$ to $+100\,^\circ C$. When operating the PFC750, proper derating and cooling are needed. The maximum case temperature under any operating condition should not exceed $100\,^\circ C$. The following is derating curve with heatsink.

Note1: $P_d$ is calculated after 1 minute of burn-in
Example with heatsink:
What is the minimum airflow necessary for a PFC750 operating at 230Vac, output current 1.923A, and a maximum ambient temperature of 35°C without heatsink?

Solution:
Given: \( V_{in} = 230\text{Vac} \), \( V_o = 390\text{Vdc} \), \( I_o = 1.923\text{A} \)

Determine Power dissipation \((P_d)\):
\[
P_d = P_{in} - P_o = P_o(1-\eta)/\eta, \quad P_d = 390\text{V} \times 1.923\text{A} \times (1-0.966)/0.966 = 26.4\text{Watts}
\]

Determine airflow:
Given: \( P_d = 26.4\text{W} \) and \( T_a = 35\text{°C} \)

Check Power Derating curve: Minimum airflow = 100 ft./min.

Verify:
- Maximum temperature rise is \( \Delta T = P_d \times R_{ca} = 26.4 \times 2.08 = 54.9\text{°C} \)
- Maximum case temperature is \( T_c = T_a + \Delta T = 89.9\text{°C} < 100\text{°C} \)

Where:
The \( R_{ca} \) is thermal resistance from case to ambient environment.
\( T_a \) is ambient temperature and \( T_c \) is case temperature.
